

Comp 352 Winter 2019

Tutorial Week 5

February 6, 2019

Outline

1. Tree: Definition
2. Binary Tree
3. Traversal
4. Problem solving
5. Priority Queue
6. Heap
7. Credits

Announcement

1. Stock Span
2. Demo
3. Assignment 1

Tree: Definition

1. Tree: $T = (V, E)$, each element in a tree has 1 parent element (with the exception of the root element) and 0 or more children elements.
2. siblings: same parent
3. ancestor \Rightarrow descendant. A node u is an ancestor of a node v if $u = v$ or u is an ancestor of the parent of v .
4. internal: one or more children
5. external: no children
6. leaves: external nodes

Tree: Definition

1. edge: $e = (u, v)$, u is the parent of v , or vice versa.
2. path: $P = v_1 \rightsquigarrow e_1 \rightsquigarrow v_2 \rightsquigarrow e_2 \rightsquigarrow \dots$

Depth

- $\text{depth}(v)$: The number of ancestors of v , excluding v itself.
- It can also be recursively defined as follows:
 - If v is the root, then the depth of v is 0.
 - Otherwise, the depth of v is one plus the depth of the parent of v .

Algorithm 1 $\text{depth}(T, v)$:

Input: T a tree

Input: v a node of T

```
1: if  $v$  is the root of  $T$  then  
2:   return 0  
3: else  
4:   return  $1 + \text{depth}(T, \text{parent}(v))$   
5: end if
```

Height

- $\text{height}(v)$: It is recursively defined as follows:
 - If v is an external, then the height of v is 0.
 - Otherwise, the height of v is one plus the maximum height of a child of v .

Height

Algorithm 2 $\text{height}(T, v)$:

Input: T a tree

Input: v a node of T

```
1: if  $v$  is an external node in  $T$  then
2:   return 0
3: else
4:    $h = 0$ 
5:   for each child  $w$  of  $v$  do
6:     if  $h < \text{height}(T, w)$  then
7:        $h = \text{height}(T, w)$ 
8:     end if
9:   end for
10:  return  $1 + h$ 
11: end if
```

Depth V.S. Height

Binary Tree

A binary tree is an ordered tree with the following properties:

1. Each internal node has at most two children (exactly two for proper (full) binary trees)
2. The children of a node are an ordered pair

Traversal

- Preorder
- Postorder
- Inorder
- Breadth first traversal

Preorder

In a preorder traversal of a tree T , the root of T is visited first and then the subtrees rooted at its children are traversed recursively.

Algorithm 3 preorder(T, v):

Input: T a tree

Input: v a node of T

- 1: visit(v)
 - 2: **for** each child w of v **do**
 - 3: preorder(T, w)
 - 4: **end for**
-

Postorder

A postorder traversal recursively traverses the subtrees rooted at the children of the root first, and then visits the root.

Algorithm 4 $\text{postorder}(T, v)$:

Input: T a tree

Input: v a node of T

- 1: **for** each child w of v **do**
 - 2: $\text{postorder}(T, w)$
 - 3: **end for**
 - 4: $\text{visit}(v)$
-

Inorder (Binary tree)

An inorder traversal recursively traverses the left subtrees rooted at the children of the root first then visits the root and then traverses the right subtree.

Algorithm 5 $\text{inOrder}(T, v)$:

Input: T a tree

Input: v a node of T

```
1: if  $\text{left}(v) \neq \text{null}$  then  
2:    $\text{inOrder}(T, \text{left}(v))$   
3: end if  
4:  $\text{visit}(v)$   
5: if  $\text{right}(v) \neq \text{null}$  then  
6:    $\text{inOrder}(T, \text{right}(v))$   
7: end if
```

Traversal

InOrder(root) visits nodes in the following order:

4, 10, 12, 15, 18, 22, 24, 25, 31, 35, 44, 50, 66, 70, 90

A Pre-order traversal visits nodes in the following order:

25, 15, 10, 4, 12, 22, 18, 24, 50, 35, 31, 44, 70, 66, 90

A Post-order traversal visits nodes in the following order:

4, 12, 10, 18, 24, 22, 15, 31, 44, 35, 66, 90, 70, 50, 25

Breadth first traversal

Traverses the tree level by level

Problem solving

Let T be an **ordered** tree with more than one node.

1. Is it possible that the preorder traversal of T visits the nodes in the same order as the postorder traversal of T ?
2. Likewise, is it possible that the preorder traversal of T visits the nodes in the reverse order of the postorder traversal of T ?

Problem solving

Give an $O(n)$ -time algorithm for computing the depth of all the nodes of a tree T , where n is the number of nodes of T .

Priority Queue

A priority queue stores a collection of entries.
Each entry is a pair (*key*, *value*).

Priority Queue Sorting

1. Selection-Sort: unsorted sequence
2. Insertion-Sort: sorted sequence
 - In-place Insertion-Sort

Heap

A heap is a **binary tree** storing keys at its nodes and satisfying the following properties:

1. Heap-Order: for every internal node v other than the root,
 $key(v) \geq key(parent(v))$
2. Complete Binary Tree
 - Complete V.S. Proper (Full)
3. Last node: rightmost node of maximum depth

Upheap

1. Find the insertion node z (the new last node)
2. Store k at z
3. Restore the heap-order property

Downheap

1. Replace the root key with the key of the last node w
2. Remove w
3. Restore the heap-order property
 - Choose the child with minimal key (why?)
